(Received 26 April 2012; published 26 November 2012)

We investigate the decay $B_s^0 \rightarrow J/\psi K^+ K^-$ for invariant masses of the $K^+ K^-$ pair in the range $1.35 < M(K^+ K^-) < 2$ GeV. The data sample corresponds to an integrated luminosity of 10.4 fb^{-1} of $p\bar{p}$ collisions at $\sqrt{s} = 1.96$ TeV accumulated with the D0 detector at the Fermilab Tevatron collider. From the study of the invariant mass and spin of the $K^+ K^-$ system, we find evidence for the two-body decay $B_s^0 \rightarrow J/\psi f_2'(1525)$ and measure the relative branching fraction of the decays $B_s^0 \rightarrow J/\psi f_2'(1525)$ and $B_s^0 \rightarrow J/\psi \phi$ to be $R_{f_2'/\phi} = 0.19 \pm 0.05(\text{stat}) \pm 0.04(\text{syst})$.

I. INTRODUCTION

In the standard model [1], the mixing of quarks originates from their interactions with the Higgs field causing the quark mass eigenstates to be different from the quark flavor eigenstates. Constraints on the mixing phases are obtained from measurements of the decays of neutral mesons. Decays to final states that are common to both partners of a neutral-meson doublet are of particular importance. The interference between the amplitude of the direct decay and the amplitude of the decay following the particle-antiparticle oscillation may lead to a CP -violating asymmetry between decays of mesons and antimesons. The decays $B_s^0 \rightarrow J/\psi X$, where X stands for a pair of

charged kaons or pions, are a sensitive probe for new phenomena because the CP -violating phase that appears in such decays is predicted in the standard model to be close to zero with high precision [2].

The first observation of the decay sequence $B_s^0 \rightarrow J/\psi f_2'(1525)$, $f_2'(1525) \rightarrow K^+ K^-$, was recently reported by LHCb [3]. The spin $J = 2$ assignment for the $K^+ K^-$ pair was based on excluding pure $J = 0$. In this article, we confirm the presence of the decay $B_s^0 \rightarrow J/\psi K^+ K^-$ with $K^+ K^-$ invariant masses $M(K^+ K^-)$ close to 1.52 GeV and we determine that the spin of the $K^+ K^-$ resonance is consistent with $J = 2$ and is preferred over $J = 0$ or $J = 1$ assignments. We identify the resonance as the $f_2'(1525)$ meson and measure the branching fraction relative to the well established decay $B_s^0 \rightarrow J/\psi \phi$.

II. DETECTOR

The D0 detector consists of a central tracking system, a calorimetry system and muon detectors, as detailed in Refs. [4–6]. The central tracking system comprises a silicon microstrip tracker (SMT) and a central fiber tracker, both located inside a 1.9 T superconducting solenoidal magnet. The tracking system is designed to optimize tracking and vertexing for pseudorapidities $|\eta| < 3$, where

§§ Deceased.

$\eta = -\ln[\tan(\theta/2)]$ and θ is the polar angle with respect to the proton beam direction.

The SMT can reconstruct the $p\bar{p}$ interaction vertex (PV) for interactions with at least three tracks with a precision of $40\ \mu\text{m}$ in the plane transverse to the beam direction and determine the impact parameter of any track relative to the PV with a precision between 20 and $50\ \mu\text{m}$, depending on the number of hits in the SMT.

The muon detector surrounds the calorimeter. It consists of a central muon system covering the pseudorapidity region $|\eta| < 1$ and a forward muon system covering the pseudorapidity region $1 < |\eta| < 2$. Both systems consist of a layer of drift tubes and scintillators inside 1.8 T toroidal magnets and two similar layers outside the toroids.

III. EVENT RECONSTRUCTION AND CANDIDATE SELECTION

The analysis presented here is based on a data sample corresponding to an integrated luminosity of $10.4\ \text{fb}^{-1}$ accumulated between February 2002 and September 2011 at the Fermilab Tevatron collider. Events are collected with single-muon and dimuon triggers. Some triggers require the presence of tracks with a large impact parameter with respect to the PV. The events selected exclusively by these triggers are removed from our sample.

Candidate $B_s^0 \rightarrow J/\psi K^+ K^-$, $J/\psi \rightarrow \mu^+ \mu^-$ events are required to include two oppositely charged muons accompanied by two oppositely charged tracks. Both muons are required to be detected in the muon chambers inside the toroidal magnet, and at least one of the muons is required to be also detected outside the toroid. Each of the four tracks is required to have at least one SMT hit. In addition, the kaon candidates are required to have at least two hits in the SMT, at least two hits in the central fiber tracker, and a total of at least eight hits in both detectors.

To form B_s^0 candidates, muon pairs in the invariant mass range $2.9 < M(\mu^+ \mu^-) < 3.3\ \text{GeV}$, consistent with J/ψ decay, are combined with pairs of oppositely charged particles (assigned the kaon mass), consistent with production at a common vertex. A kinematic fit under the B_s^0 decay hypothesis constrains $M(\mu^+ \mu^-)$ to the Particle Data Group [1] value of the J/ψ mass and the four tracks to a common vertex. The trajectories of the four B_s^0 decay products are adjusted according to this kinematic fit. In events where multiple candidates satisfy these requirements, we select the candidate with the best fit probability. The χ^2 of the fit is required to be less than 15, for a total number of degrees of freedom of 4. We require that the transverse momenta of the B_s^0 and K^\pm mesons are larger than 8 and 0.7 GeV, respectively. To suppress background from the decay $B^0 \rightarrow J/\psi K^*(892)$, we require the kaon pair to have an invariant mass greater than 1 GeV under the $K^\pm \pi^\mp$ hypothesis.

To reconstruct the PV, we select tracks that do not originate from the candidate B_s^0 decay and apply a

constraint to the average beam-spot position [4] in the transverse plane. We define the signed decay length of a B_s^0 meson, L_{xy}^B , as the vector pointing from the PV to the decay vertex, projected on the B_s^0 transverse momentum p_T . The proper decay time of a B_s^0 candidate is given by $t = M_{B_s} \vec{L}_{xy}^B \cdot \vec{p}/(p_T^2)$ where M_{B_s} is the world-average B_s^0 mass [1] and \vec{p} is the particle momentum. To increase B_s^0 signal purity and reject prompt background, we require the proper decay length to be greater than $200\ \mu\text{m}$. The distribution of the uncertainty on the proper decay length peaks around $25\ \mu\text{m}$ and has a long tail extending to several hundred microns. To remove poorly reconstructed events in the tail, we require the uncertainty of the proper decay length to be less than $100\ \mu\text{m}$.

IV. MONTE CARLO SAMPLES

Some aspects of this analysis require information that cannot be derived from data. We rely on Monte Carlo (MC) simulated samples to derive templates of the distributions of the signal $B_s^0 \rightarrow J/\psi f_2'(1525)$ and of the main background components, and to derive the detector acceptance as a function of decay angles and the relative acceptance for the decays $B_s^0 \rightarrow J/\psi \phi$ and $B_s^0 \rightarrow J/\psi f_2'(1525)$.

We use PYTHIA [7] to generate B_s^0 mesons and EVTGEN [8] to simulate their decay. In all simulated samples the final states are assumed to have no polarization. The samples have been processed by the detector simulation and the standard event reconstruction. To take into account the effects of the instantaneous luminosity, the MC samples are overlaid with data events collected during random beam crossings. We have generated events containing the decays $B_s^0 \rightarrow J/\psi f_2'(1525)$, $B_s^0 \rightarrow J/\psi \phi$, $B^0 \rightarrow J/\psi K_2^*(1430)$, and $B^0 \rightarrow J/\psi K_0^*(1430)$.

V. $B_s^0 \rightarrow J/\psi K^+ K^-$ SIGNAL EXTRACTION

The distribution of the B_s^0 candidate mass $M(J/\psi K^+ K^-)$ as a function of $M(K^+ K^-)$ for accepted events is shown in Fig. 1. The data show a structure consistent with the decay $B_s^0 \rightarrow J/\psi f_2'(1525)$. Another possibility for the observed structure near $M(K^+ K^-) = 1.5\ \text{GeV}$ is the decay $B_s^0 \rightarrow J/\psi f_0(1500)$. The two states have very different branching fractions to $\pi^+ \pi^-$ and $K^+ K^-$. The branching fractions [1] are $\mathcal{B}(f_0(1500) \rightarrow \pi^+ \pi^-) = (34.9 \pm 2.3)\%$, $\mathcal{B}(f_0(1500) \rightarrow K^+ K^-) = (8.6 \pm 1.0)\%$, $\mathcal{B}(f_2'(1525) \rightarrow \pi^+ \pi^-) = (0.82 \pm 0.15)\%$, and $\mathcal{B}(f_2'(1525) \rightarrow K^+ K^-) = (88.7 \pm 2.2)\%$. If the $M(K^+ K^-)$ peak is due to the $f_0(1500)$, a larger peak is expected near $M(\pi^+ \pi^-) = 1.5\ \text{GeV}$. If the $M(K^+ K^-)$ peak is due to the $f_2'(1525)$ meson, a negligibly small peak is expected in the $M(\pi^+ \pi^-)$ distribution. From the lack of significant B_s^0 signal in the $\pi^+ \pi^-$ channel, presented in Fig. 2, we conclude that the observed state is not the $f_0(1500)$ meson.

However, as observed by others [3,9], a similar distribution may also result from decays of B^0 mesons where the

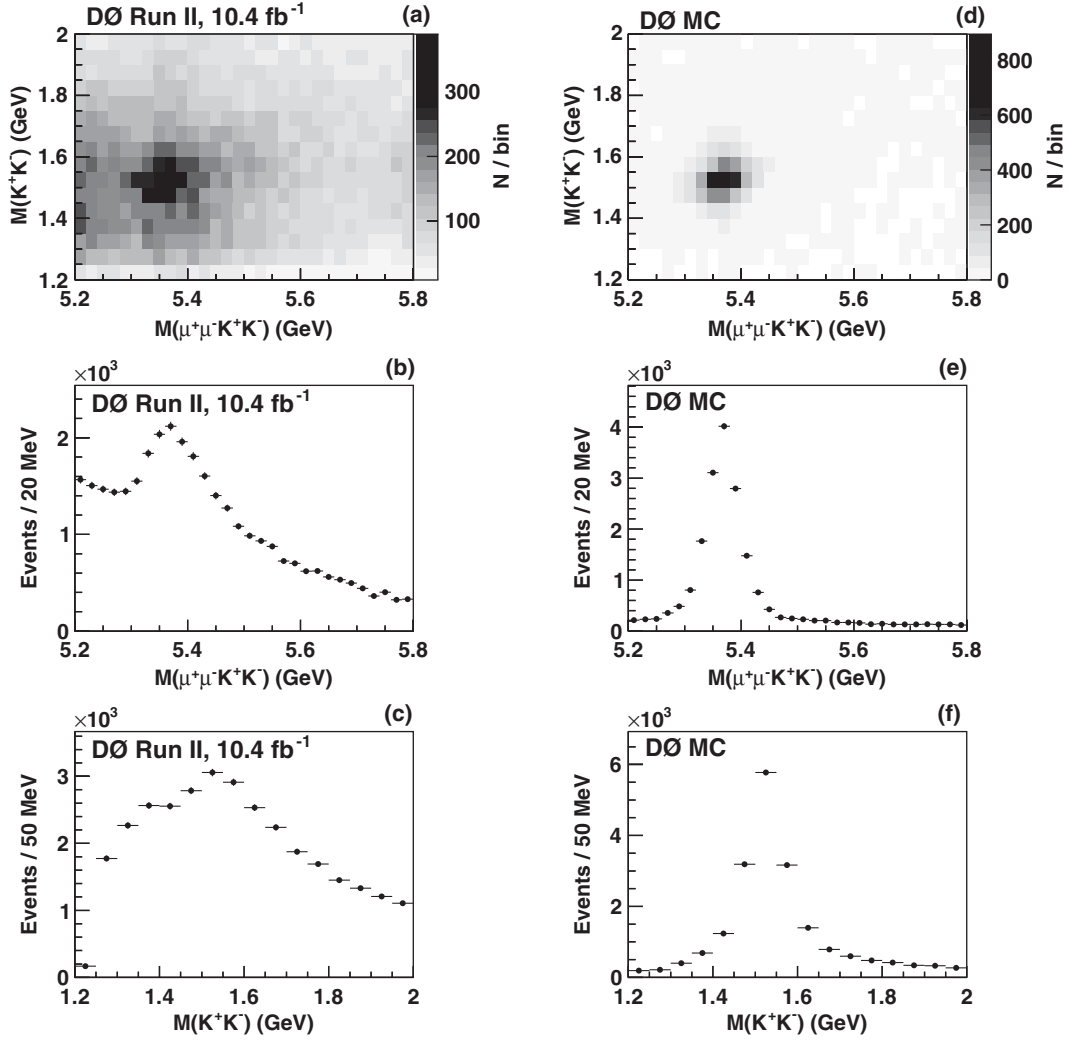

FIG. 1. (a) Invariant mass of the B_s^0 candidates as a function of $M(K^+K^-)$ as well as (b) and (c) one-dimensional projections. The observed structure is consistent with a decay $B_s^0 \rightarrow J/\psi K^+K^-$ proceeding through $f_2'(1525)$ or $f_0(1500)$ mesons. (d) Invariant mass of the B_s^0 mesons as a function of $M(K^+K^-)$ for the simulated decay $B_s^0 \rightarrow J/\psi f_2'(1525)$ as well as (e) and (f) one-dimensional projections.

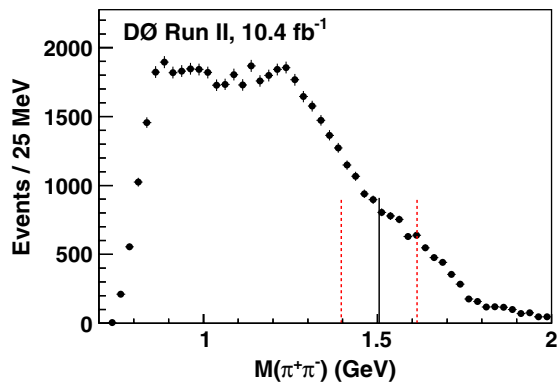

FIG. 2 (color online). Distribution of the invariant mass $M(\pi^+\pi^-)$. The solid and dashed vertical lines represent the world-average mass and the natural width of the $f_0(1500)$ meson [1], respectively.

J/ψ meson is accompanied by a K^* resonance, and a pion from the decay $K^* \rightarrow K^\pm \pi^\mp$ is assigned the kaon mass.

There are two $K_J^*(1430)$ states, degenerate in mass but differing in width, $\Gamma = 0.109 \pm 0.005$ GeV for $J = 2$ and $\Gamma = 0.27 \pm 0.08$ GeV for $J = 0$ [1]. Simulated distributions of B_s^0 mass versus $M(K^+K^-)$ for misidentified decays $B^0 \rightarrow J/\psi K_2^*(1430)$ and $B^0 \rightarrow J/\psi K_0^*(1430)$ are shown in Fig. 3. In the case of $J = 0$, we use the full $I = 1/2$ $K\pi$ elastic scattering S -wave amplitude [9] composed of $K_0^*(1430)$ and a nonresonant term.

As seen in Fig. 3, the decays $B^0 \rightarrow J/\psi K_J^*(1430)$ with $J = 0, 2$ can mimic the decay $B_s^0 \rightarrow J/\psi f_2'(1525)$, with the apparent B_s^0 mass peak position increasing with $M(K^+K^-)$. We take this peaking background into account by constructing templates of the B_s^0 mass distribution in steps of the K^+K^- invariant mass of 50 MeV. Examples of the templates are shown in Figs. 4 and 5. Figure 6 shows the

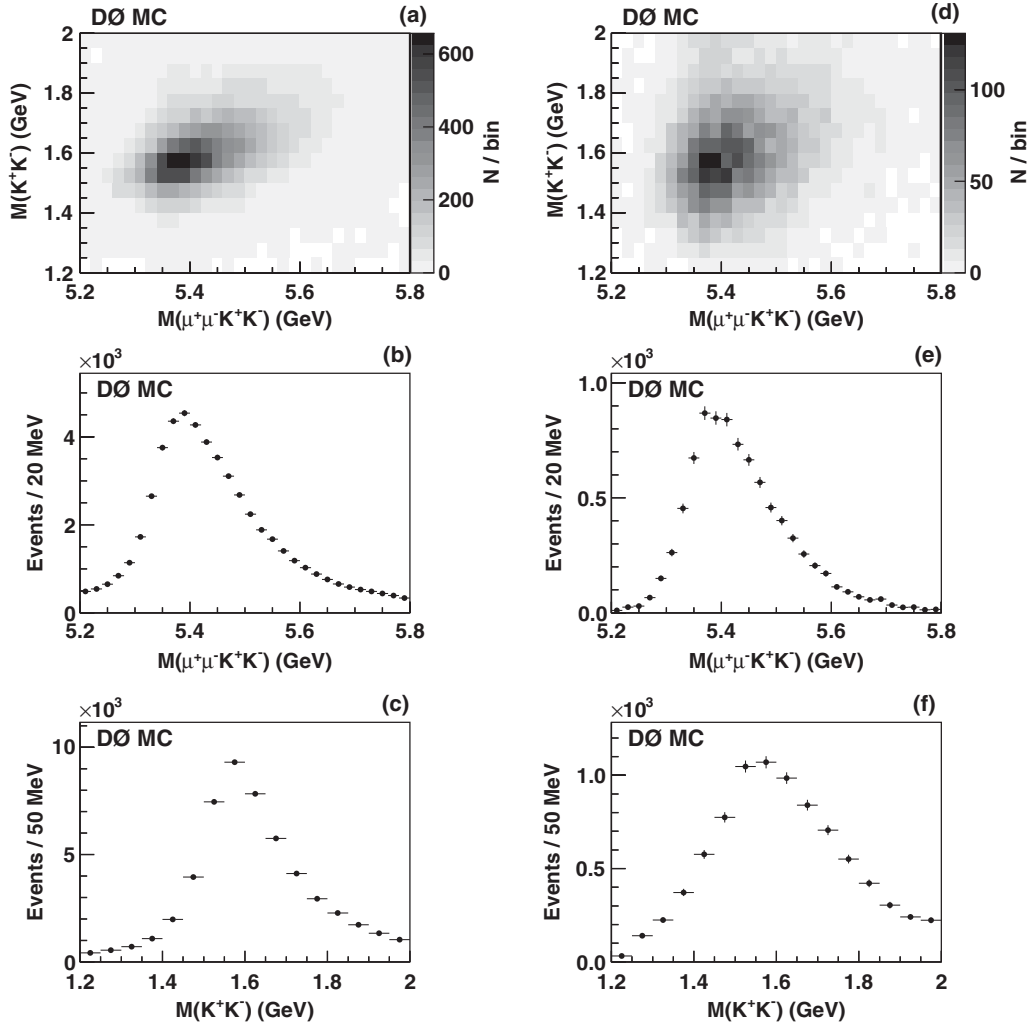

FIG. 3. (a) Invariant mass of the B_s^0 candidates versus $M(K^+K^-)$ for simulated decay $B^0 \rightarrow J/\psi K_2^*(1430)$; $K_2^* \rightarrow \pi^\pm K^\mp$, with the pion assigned the kaon mass, as well as (b) and (c) one-dimensional projections. (d) $K\pi$ S -wave contribution [9] to the decay $B^0 \rightarrow J/\psi K^\pm \pi^\mp$, with the pion assigned the kaon mass as well as (e) and (f) one-dimensional projections.

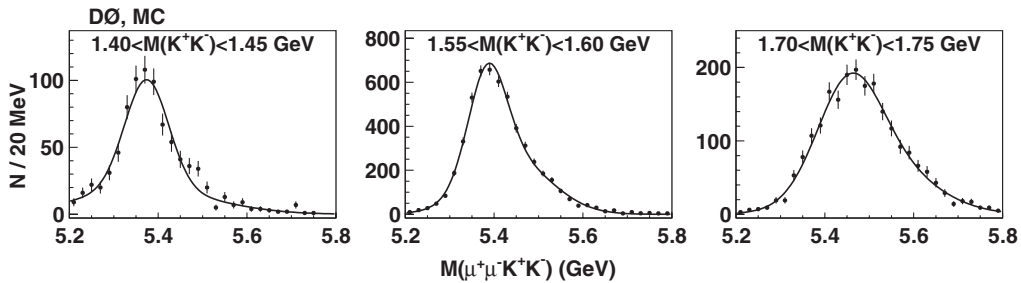

FIG. 4. Invariant mass of B^0 mesons from the simulated decay $B^0 \rightarrow J/\psi K_2^*(1430)$, $K_2^*(1430) \rightarrow K^\pm \pi^\mp$, where the pion is assigned the kaon mass, for a sampling of different $M(K^+K^-)$ ranges. The distributions are fitted with a sum of two Gaussian functions with free masses, widths, and normalizations.

simulated $B_s^0 \rightarrow J/\psi f_2'(1525)$ signal in the same $M(K^+K^-)$ ranges, with fits to a sum of two Gaussian functions.

Other possible sources of peaking background include B -meson decays to J/ψ mesons accompanied by the $J = 1$ and $J = 3$ resonances $K^*(1410)$ and $K_3^*(1780)$.

The former decays predominantly to $K^*(892)$. When the kaon mass is used for both tracks, the latter resonance would peak at $M(K^+K^-)$ greater than 1.78 GeV.

The candidate mass distribution in the range $1.45 < M(K^+K^-) < 1.60$ GeV and $|\cos\psi| < 0.8$ is shown in Fig. 7, where ψ is the helicity angle defined in Sec. VI.

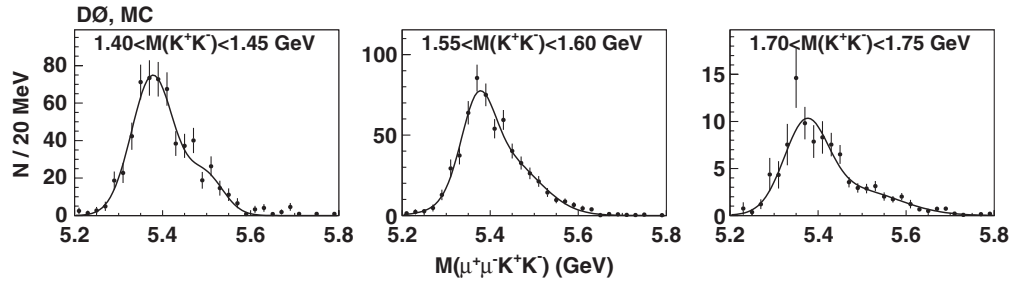

FIG. 5. Invariant mass of B^0 mesons from the simulated $K\pi$ S -wave contribution [9] to the decay $B^0 \rightarrow J/\psi K^\pm \pi^\mp$, where the pion is assigned the kaon mass, for a sampling of different $M(K^+K^-)$ ranges. The distributions are fitted with a sum of two Gaussian functions with free masses, widths, and relative normalizations.

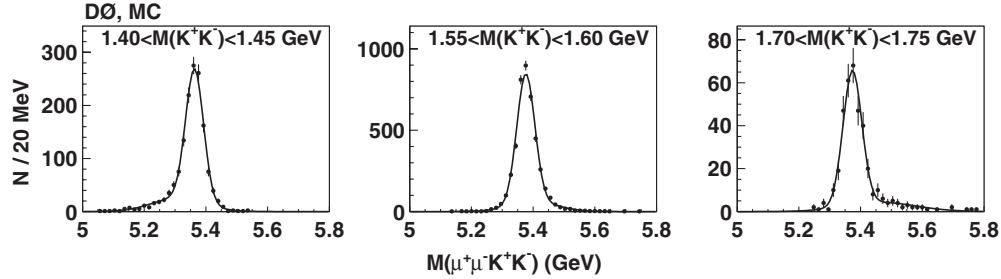

FIG. 6. Invariant mass of B_s^0 mesons from the simulated decay $B_s^0 \rightarrow J/\psi f_2'(1525)$ for a sampling of different ranges of $M(K^+K^-)$. The distributions are fitted with a sum of two Gaussian functions with free masses, widths, and relative normalization.

A fit of templates for the $B_s^0 \rightarrow J/\psi K^+ K^-$ decay, the $B^0 \rightarrow J/\psi K_2^*(1430)$ and S -wave $K\pi$ background and a linear combinatorial background, yields 534 ± 101 $B_s^0 \rightarrow J/\psi K^+ K^-$ events. The relative rate of the S and D $K\pi$ wave is constrained to the ratio of 3:2 reported in Ref. [9].

To extract the B_s^0 signal yield, we use the B_s^0 mass distribution for $M(K^+K^-)$ between 1.35 and 2 GeV. We fit the simulated signal templates to the data, with the mass parameter of the core Gaussian function in each $M(K^+K^-)$ bin scaled by a factor of 0.9982 ± 0.0008 obtained by matching the simulation and data as shown in Fig. 7. Figure 8 shows the B_s^0 mass fits using the templates for the signal $B_s^0 \rightarrow J/\psi f_2'(1525)$ and for the $B^0 \rightarrow J/\psi K_2^*$

(1430) and $B^0 \rightarrow J/\psi K_0^*(1430)$ reflections. In these fits we allow the relative rates of the S and D $K\pi$ contributions to vary. Note that a nonresonant K^+K^- component is implicitly included in the signal part of these fits. In addition to the peaking background there is a background due to random combinations and partially reconstructed B -meson decays, described by a linear function. We allow the relative normalization of the two K_2^* states to vary in each fit. The normalization parameters of the B_s^0 signal and background components are not constrained to be positive in order to obtain unbiased results for rates close to zero. We have conducted toy MC ensemble tests and we confirm that there are no biases on signal yield introduced by the described fitting procedure.

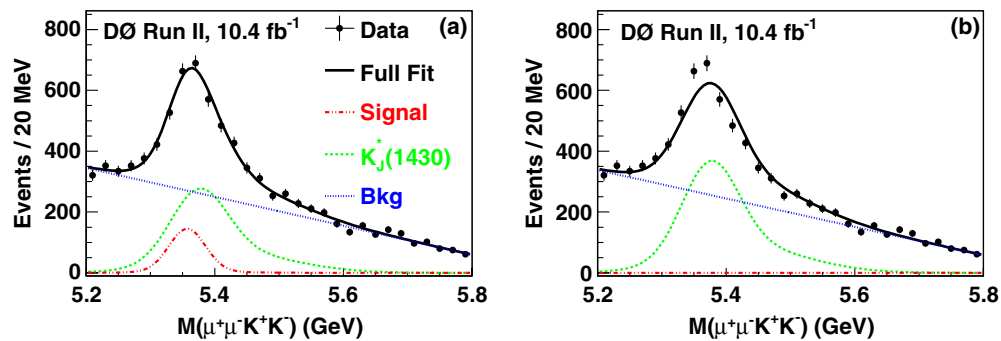

FIG. 7 (color online). Invariant mass of the B_s^0 candidates with $1.45 < M(K^+K^-) < 1.6$ GeV. Curves show (a) the result of the fit allowing for a free B_s^0 signal yield (dashed-dotted lines) and a background composed of a 3:2 mixture of $B^0 \rightarrow J/\psi K^\pm \pi^\mp$ decays with the $K^\pm \pi^\mp$ system in the $J = 0$ and $J = 2$ states (dashed lines) and a combinatorial component described by a linear function (dotted lines), and (b) the result of the fit assuming the same background model but setting the B_s^0 signal rate to zero.

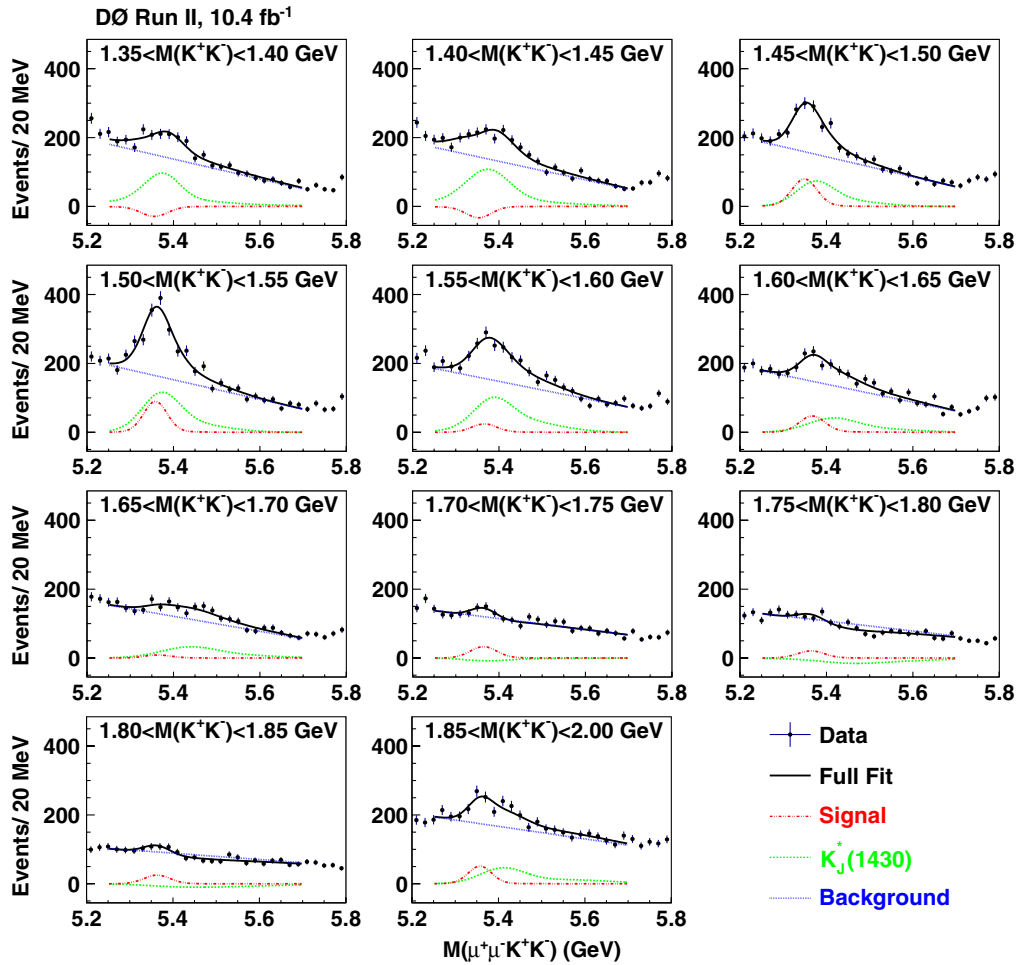

FIG. 8 (color online). Invariant mass of candidates for the decay $B_s^0 \rightarrow J/\psi K^+ K^-$ in a sampling of different $M(K^+ K^-)$ ranges. Each fit uses a template derived from the B_s^0 signal simulation, a combination of the templates for the decays $B^0 \rightarrow J/\psi K_j^*(1430)$, $K_j^*(1430) \rightarrow K^\pm \pi^\mp$, $J = 1, 2$, as shown in Figs. 4 and 5, and a linear function describing the combinatorial background. The fit is performed in the range $5.25 < M(J/\psi K^+ K^-) < 5.7$ GeV, used to avoid the steeply falling background from multibody decays of B mesons at lower masses and the steeply rising background from decays $B^\pm \rightarrow J/\psi K^\pm$ at higher masses. Neither the B_s^0 signal nor background components are constrained to positive values in order to obtain unbiased results for rates close to zero.

As seen from Fig. 8, the fitted yields for the $B^0 \rightarrow J/\psi K_2^*(1430)$ and $B^0 \rightarrow J/\psi K_0^*(1430)$ decays exceed the B_s^0 signal in most of the 11 subsamples, although the data do not provide a significant constraint on their relative strength. For an independent study of this background, we select events in the range $5.4 < M(J/\psi K^+ K^-) < 5.6$ GeV, where the $B^0 \rightarrow J/\psi K_j^*(1430)$ decays dominate over the B_s^0 signal. In Fig. 9 we show the $M(K^\pm \pi^\mp)$ distribution for these events. A fit of a relativistic Breit-Wigner $J = 2$ resonance at a fixed mass of 1.43 GeV and with a floating width, over a background described by a second-order polynomial function, yields 3386 ± 390 $K^*(1430)$ resonance events. This is in agreement with the total number of events ascribed to the $K^*(1430)$ reflection in this mass range. The best fit result for the width is $\Gamma = 0.162 \pm 0.019$ GeV that is in between the widths of the $J = 2$ and $J = 0$ states. This study shows that we cannot establish the dominance of one background

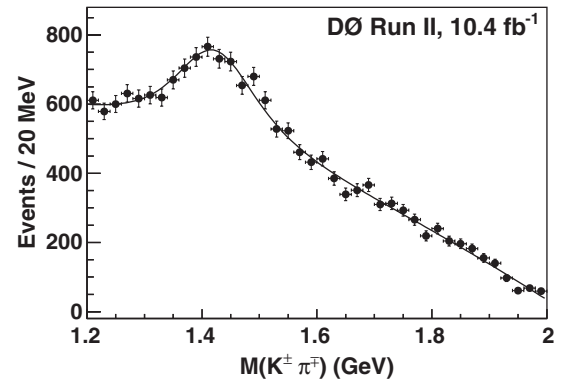

FIG. 9. Invariant mass distribution of the meson pair from the B_s^0 candidates in the mass range $5.4 < M(J/\psi K^+ K^-) < 5.6$ GeV, under the $K^\pm \pi^\mp$ hypothesis. The curve shows the fit of a relativistic Breit-Wigner $J = 2$ resonance at a fixed mass of 1.43 GeV and with a floating width, over a background described by a second-order polynomial function.

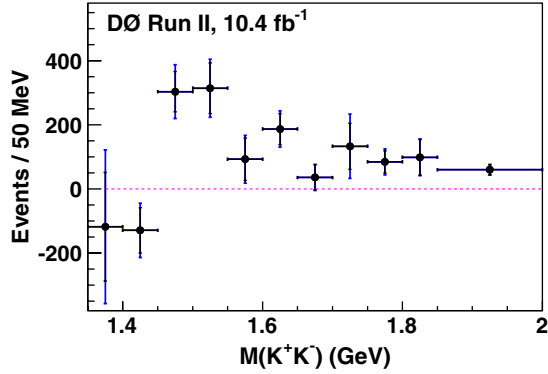

FIG. 10 (color online). The B_s^0 signal yield as a function of $M(K^+K^-)$ obtained from the fits shown in Fig. 8. The outer and inner error bars correspond to the statistical uncertainties with and without systematic uncertainties added in quadrature.

component over the other with the present data. Figure 10 shows the B_s^0 signal yield versus $M(K^+K^-)$ from data after taking into account the $B^0 \rightarrow J/\psi K_2^*(1430)$ and $B^0 \rightarrow J/\psi K_0^*(1430)$ templates and a linear background.

VI. SPIN OF K^+K^- STATE

In Sec. V, we have presented evidence for the decay $B_s^0 \rightarrow J/\psi K^+K^-$ in the range $M(K^+K^-) > 1.35$ GeV. The $M(K^+K^-)$ distribution peaks near 1.5 GeV. In this section we study the spin of the K^+K^- system in the range $1.45 < M(K^+K^-) < 1.60$ GeV.

A K^+K^- system can be in any natural parity state, $J^P = 0^+, 1^-, 2^+$, etc. We consider the values $J = 0, 1$, and 2 for the spin of the observed structure.

The final state can be described by three independent angles. We define them as follows: θ_H is the angle between the direction of μ^+ and B_s^0 direction in the J/ψ rest frame, ψ is the angle of the K^+ meson with respect to the B_s^0 direction in the K^+K^- rest frame, and ϕ_H is the angle between the two decay planes, as shown in Fig. 11. The angular distribution for the decay of a spinless meson into the spin-one meson J/ψ and a meson of unknown spin J can be expressed in terms of $H_1 = \cos\theta_H$, $H_2 = \cos\psi$, and ϕ_H as follows [10]:

$$\frac{d\Gamma}{d\Omega} \propto |\sum A_{Jm} Y_1^m(H_1, \phi_H) Y_J^m(-H_2, 0)|^2 D(\Omega), \quad (1)$$

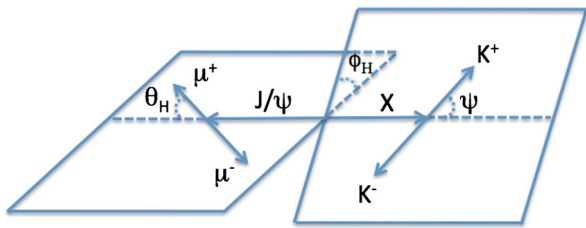

FIG. 11 (color online). Definition of the decay angles θ_H , ϕ_H , and ψ in the helicity basis for the sequential decay $B_s^0 \rightarrow J/\psi X$, $J/\psi \rightarrow \mu^+ \mu^-$, $X \rightarrow K^+ K^-$.

where Y_J^m are spherical harmonics, A_{Jm} are complex amplitudes corresponding to spin J and helicity m , and Ω is either H_1 , ϕ_H or H_2 , and the sum extends over equal helicities of the daughter particles, $m = 0$ or $m = \pm 1$. The factor D is the acceptance of the event selection. Its dependence on the three angular variables is shown in Fig. 12.

Due to limited statistics and a large background, we focus on the $\cos\psi$ distribution obtained by integrating the angular distribution over $\cos\theta_H$ and ϕ_H , taking into account the variation of the acceptance as a function of $\cos\theta_H$. We extract the B_s^0 signal rate as a function of $|\cos\psi|$ by fitting the candidate mass in five regions of $|\cos\psi|$. The data and fit results are shown in Fig. 13. The resulting distribution, corrected for acceptance, is shown in

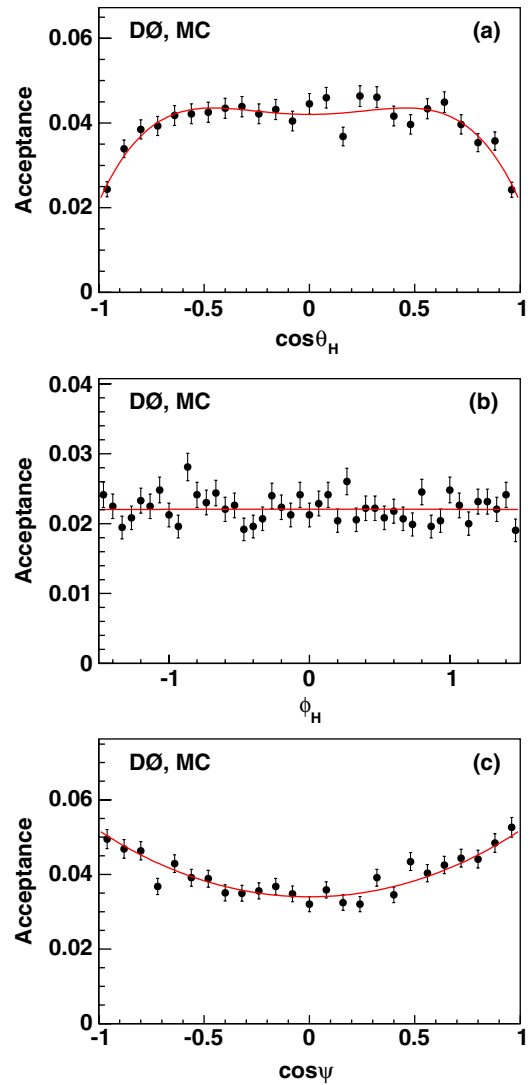

FIG. 12 (color online). Angular dependence of the detection and event selection acceptance of the decay $B_s^0 \rightarrow J/\psi f_2'(1525)$ from simulations as a function of (a) $\cos\theta_H$, (b) ϕ_H , and (c) $\cos\psi$. The acceptance is found to be independent of the angle ϕ_H . For $\cos\theta_H$ and $\cos\psi$, we fit the acceptance dependence with symmetric fourth-order polynomial functions.

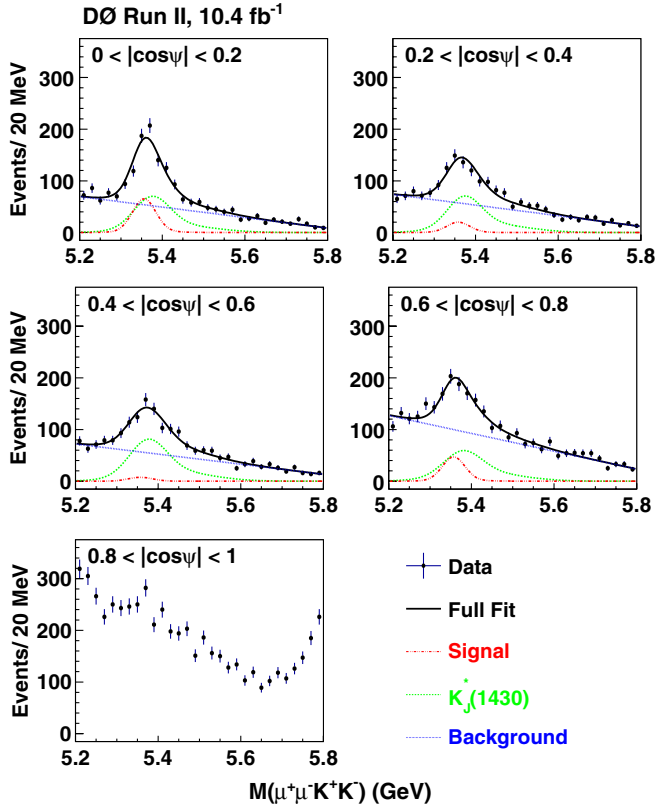

FIG. 13 (color online). The B_s^0 mass distribution in five intervals of $|\cos\psi|$ as shown. The fits assume a two-Gaussian B_s^0 signal template and a background composed of a reflection of the $B^0 \rightarrow J/\psi K^\pm \pi^\mp$ decay and a linear component. There is a steeply falling background from multibody decays of B mesons at lower masses and a steeply rising background from decays $B^\pm \rightarrow J/\psi K^\pm$ at higher masses. These backgrounds are particularly acute for $\cos(\psi) > 0.8$ making it impossible to obtain a reliable fit in this region.

Fig. 14. Systematic uncertainties due to the shape of combinatorial background, signal model, and acceptance, are added in quadrature. In the region $|\cos\psi| > 0.8$, the large background prevents obtaining a reliable fit.

For $J = 0$, the expected distribution is isotropic. For $J = 1$, the $\cos\psi$ distribution without the acceptance factor is given by

$$\frac{d\Gamma}{d\cos\psi} \propto F_{10}(2\cos^2\psi) + (1 - F_{10})\sin^2\psi, \quad (2)$$

where F_{10} is the ratio of the rate $J = 1, m = 0$ to the total $J = 1$ rate. For a superposition of $J = 0$ and 2, with a free relative normalization, the $\cos\psi$ distribution is obtained from

$$\begin{aligned} \frac{d\Gamma}{d\cos\psi} &\propto \left| \sqrt{F_{20}(1 - F_0)(5/4)(3\cos^2\psi - 1) + \exp(i\delta_0)\sqrt{F_0}} \right|^2 \\ &+ \frac{15}{2}(1 - F_{20})(1 - F_0)\sin^2\psi(1 - \sin^2\psi), \end{aligned} \quad (3)$$

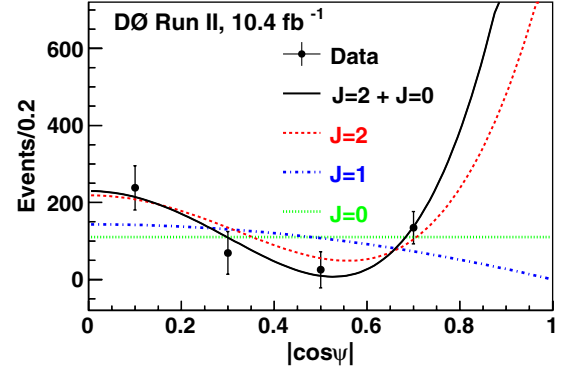

FIG. 14 (color online). The $|\cos\psi|$ distribution for the decay $B_s^0 \rightarrow J/\psi X$, $X \rightarrow K^+K^-$ in the range $1.45 < M(K^+K^-) < 1.6$ GeV. The curves are best fits assuming pure $J = 0$ (dashed line), pure $J = 1$ (dashed-dotted line), and pure $J = 2$ (solid line).

where F_{20} is the ratio of the rate $J = 2, m = 0$ to the total $J = 2$ rate, and F_0 is the $J = 0$ fraction with relative phase angle δ_0 .

Figure 14 shows that the data favor $J = 2$, hence the peak is identified with the $f_2'(1525)$ meson. The fit probabilities for pure $J = 0$ and pure $J = 1$ are 2.8×10^{-2} and 9.8×10^{-3} , respectively. For $J = 2$ the fit probability is 0.27. The data are also consistent with a coherent superposition of $J = 0$ and $J = 2$ states. With $F_{20} = 1$, we obtain the S -wave fraction of $F_0 = 0.06 \pm 0.16$ and a fit probability of 0.37.

VII. SIGNAL YIELD

The measured decay rate of a particle resonance as a function of the invariant mass of the final state is described by the relativistic Breit-Wigner function (RBW) [1] convoluted with detector resolution.

To obtain the detector resolution, we use simulated $B_s^0 \rightarrow J/\psi f_2'(1525)$ decays where the J/ψ is forced to decay into two muons and the $f_2'(1525)$ into two kaons. The fitted $M(K^+K^-)$ distribution for the simulation is shown in Fig. 15. Fixing the mass and natural width parameters at their input values, $M = 1525$ MeV and $\Gamma_0 = 73$ MeV, and using the range parameter [1] $R = 5.0$ GeV $^{-1}$, we obtain $\sigma(M) = 22 \pm 1$ MeV.

We fit the B_s^0 signal yield versus $M(K^+K^-)$ from data, as shown in Fig. 10, to an incoherent sum of the $J = 2$ component and a constant continuum term. The result is shown in Fig. 16. The fit yields $629 \pm 157 f_2'(1525)$ events and 345 ± 76 events for the constant term in the mass range $1.4 < M(K^+K^-) < 1.7$ GeV. The fraction of the nonresonant term, assumed to be the S wave, in this mass range is 0.35 ± 0.09 .

VIII. RATIO OF $\mathcal{B}(B_s^0 \rightarrow J/\psi f_2'(1525))$ AND $\mathcal{B}(B_s^0 \rightarrow J/\psi \phi)$

To determine an absolute branching fraction for the $B_s^0 \rightarrow J/\psi f_2'(1525)$ decay, efficiencies, branching

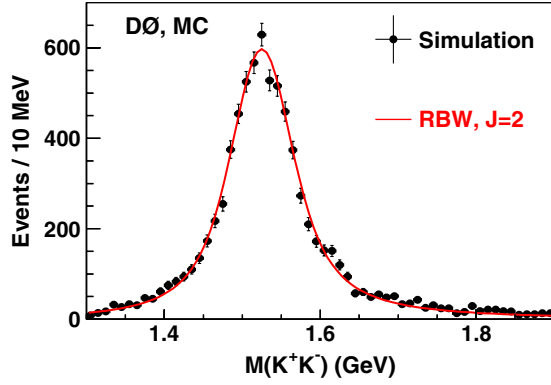

FIG. 15 (color online). The $M(K^+K^-)$ distribution from the simulation of the decay $B_s^0 \rightarrow J/\psi f_2'(1525)$ fitted by the relativistic Breit-Wigner function [1].

fractions, and the cross section need to be known, as well as the integrated luminosity. However, terms common to the $B_s^0 \rightarrow J/\psi f_2'(1525)$ and the $B_s^0 \rightarrow J/\psi \phi$ branching fractions cancel in their ratio. A measurement of the relative branching fraction $R_{f_2'/\phi}$ requires the yields of the two decays, $N_{B_s^0 \rightarrow J/\psi f_2'(1525)}$ and $N_{B_s^0 \rightarrow J/\psi \phi}$, and the reconstruction efficiencies of the two decay modes, $\varepsilon_{\text{reco}}^{B_s^0 \rightarrow J/\psi \phi}$ and $\varepsilon_{\text{reco}}^{B_s^0 \rightarrow J/\psi f_2'(1525)}$:

$$R_{f_2'/\phi} = \frac{\mathcal{B}(B_s^0 \rightarrow J/\psi f_2'(1525); f_2'(1525) \rightarrow K^+K^-)}{\mathcal{B}(B_s^0 \rightarrow J/\psi \phi; \phi \rightarrow K^+K^-)} = \frac{N_{B_s^0 \rightarrow J/\psi f_2'(1525)} \times \varepsilon_{\text{reco}}^{B_s^0 \rightarrow J/\psi \phi}}{N_{B_s^0 \rightarrow J/\psi \phi} \times \varepsilon_{\text{reco}}^{B_s^0 \rightarrow J/\psi f_2'(1525)}} \quad (4)$$

where $N_{B_s^0 \rightarrow J/\psi f_2'(1525)}$ is determined in the mass range $1.4 < M(K^+K^-) < 1.7$ GeV and $N_{B_s^0 \rightarrow J/\psi \phi}$ in the mass range $1.01 < M(K^+K^-) < 1.03$ GeV. The only difference in the event selection for the two channels is the

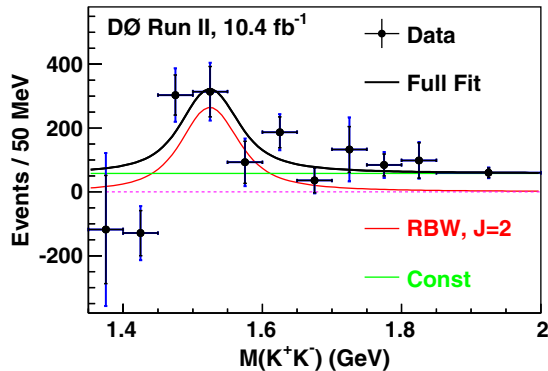

FIG. 16 (color online). Fit to the B_s^0 yield versus $M(K^+K^-)$ as obtained in Fig. 10. The full fit to $B_s^0 \rightarrow J/\psi K^+K^-$ includes a $f_2'(1525)$ signal described by a relativistic Breit-Wigner and nonresonant constant term for the S wave. The outer and inner error bars correspond to the statistical uncertainties with and without systematic uncertainties added in quadrature.

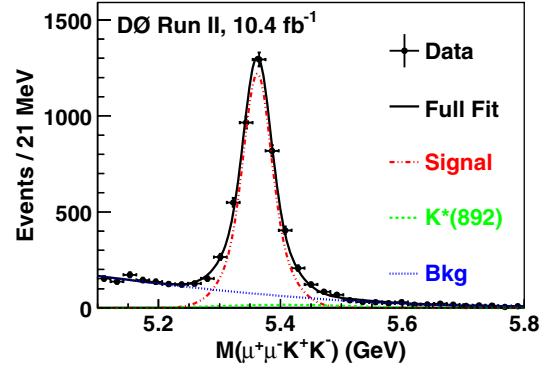

FIG. 17 (color online). Invariant mass distribution of B_s^0 candidates with $ct > 200 \mu\text{m}$ for events in the mass range $1.01 < M(K^+K^-) < 1.03$ GeV. A fit to a sum of a double Gaussian $B_s^0 \rightarrow J/\psi \phi$ signal (dashed-dotted line), a quadratic combinatorial background (dotted line), and the reflection of the decay $B^0 \rightarrow J/\psi K^*(892)$ (dashed line) is used to extract the B_s^0 yield.

$M(K\pi) > 1$ GeV condition applied for the $J/\psi f_2'(1525)$ candidates.

The yield of the $B_s^0 \rightarrow J/\psi \phi$ decay is determined by fitting the data, shown in Fig. 17, with a double Gaussian function for the signal, a second-order polynomial for background, and the reflection of the decay $B_d^0 \rightarrow J/\psi K^*$ taken from simulations. The total number of $B_s^0 \rightarrow J/\psi \phi$ events is 4064 ± 105 .

We use simulated samples of the two decay processes to determine the reconstruction efficiencies. For the decay $B_s^0 \rightarrow J/\psi f_2'(1525)$ the efficiency is measured to be $(0.122 \pm 0.002)\%$ and for the decay $B_s^0 \rightarrow J/\psi \phi$ it is $(0.149 \pm 0.002)\%$ (where the uncertainties are due to MC statistics), yielding $R_{f_2'/\phi} = 0.19 \pm 0.05(\text{stat})$.

The denominator in Eq. (4) may include a contribution from the K^+K^- S wave, and no correction is made, allowing the ratio to be recalculated for different S -wave fraction inputs.

IX. SYSTEMATIC UNCERTAINTIES

The main contributions to systematic uncertainties are summarized in Table I. They are evaluated as follows:

- (i) $K_0^*(1430)$ width: We vary the K_0^* width within its uncertainty of 0.08 GeV [1].
- (ii) $K_0^*(1430)$ and $K_2^*(1430)$ templates: We vary the shape of the K_0^* and K_2^* templates by altering the widths of the dominant Gaussian component within statistical uncertainties.
- (iii) Combinatorial background shape: As an alternative, we use a second-order polynomial to describe the combinatorial background. We also vary the fitting mass range from 5.25–5.70 to 5.2–5.8 GeV.
- (iv) Signal shape: We vary the B_s^0 mass scale within its uncertainty in data of 0.08% and the width of the core Gaussian component by $\pm 10\%$.

TABLE I. Sources of systematic relative uncertainty on $R_{f'_2/\phi}$.

Source	Uncertainty (%)
$K_0^*(1430)$ width	5
$K_0^*(1430)$ and $K_2^*(1430)$ templates	10
Combinatorial background shape	10
Signal shape	12
Trigger efficiency	3
$M(K^+K^-)$ dependence of efficiency	2
Helicity dependence of efficiency	3
$f'_2(1525)$ mass	3
$f'_2(1525)$ natural width	1
$B_s^0 \rightarrow J/\psi\phi$ signal shape	4
Total	20

- (v) *Trigger efficiency*: Due to the mass difference between the $f'_2(1525)$ and ϕ resonances, there is a small difference between average muon momenta in the two channels. Approximately 3% more $J/\psi\phi$ events have a leading muon with $p_T > 15$ GeV and about 3% more $J/\psi\phi$ events have both muons with $p_T > 3$ GeV. We therefore estimate that there is approximately a 3% difference in the fraction of events that can be accepted by the trigger between the $J/\psi\phi$ and $J/\psi f'_2(1520)$ signals. Trigger simulations confirm this estimate. We apply the 3% correction to $R_{f'_2/\phi}$ and assign an absolute 3% systematic uncertainty.
- (vi) *$M(K^+K^-)$ dependence of efficiency*: The $M(K^+K^-)$ dependence of the efficiency for reconstructing the $f'_2(1520)$ resonance is obtained from a simulation. We assign a 2% uncertainty due to the statistical precision of the MC sample.
- (vii) *Helicity dependence of efficiency*: The $B_s^0 \rightarrow J/\psi\phi$ signal acceptance is obtained from a MC sample generated under the assumption that the final state is not polarized, i.e., with the final state distributed uniformly in helicity angle $\cos\theta_H$. We compare this signal acceptance with distributions corresponding to pure helicity 0 and 1 and assign a systematic uncertainty equal to the difference.

- (viii) *$f'_2(1525)$ mass and natural width*: The uncertainty on the mass of the $f'_2(1525)$ resonance of 5 MeV [1] leads to the uncertainty on $R_{f'_2/\phi}$ of 3%, while the uncertainty on the natural width of 6 MeV leads to the uncertainty on $R_{f'_2/\phi}$ of 0.7%.
- (ix) *$B_s^0 \rightarrow J/\psi\phi$ signal shape*: The $B_s^0 \rightarrow J/\psi\phi$ signal yield is sensitive to the signal mass model because of the presence of the $B_s^0 \rightarrow J/\psi K^*(890)$ reflection that peaks near the signal. We assign the systematic uncertainty as one half of the difference between fit results for single and double Gaussian distributions for the signal mass model.

X. SUMMARY AND DISCUSSION

We confirm the observation of the decay $B_s^0 \rightarrow J/\psi f'_2(1525)$ previously observed by the LHCb Collaboration [3] and measure the ratio of branching fractions of the decays $B_s^0 \rightarrow J/\psi f'_2(1525)$ and $B_s^0 \rightarrow J/\psi\phi$ to be $R_{f'_2/\phi} = 0.19 \pm 0.05(\text{stat}) \pm 0.04(\text{syst})$. The fit to the background-subtracted signal $B_s^0 \rightarrow J/\psi K^+ K^-$, assuming an incoherent sum of the $J = 2$ resonance $f'_2(1525)$ and a constant continuum term, assigns the fraction of 0.35 ± 0.09 to the constant term. The fit to the helicity angle ψ in the $K^+ K^-$ rest frame finds the $K^+ K^-$ resonance to be consistent with $J = 2$ with a fit probability of 0.27 and preferred over $J = 0$ or $J = 1$, for which the fit probabilities are 2.8×10^{-2} and 9.8×10^{-3} , respectively.
